A photograph of our "Milky Way" Galaxy taken with a wide-angle fisheye lens. The center of the image is in the direction of our Galactic Center which lies in the direction of the constellation Sagittarius. The dark bands running through the center of the broader band of "milky" light are due to absorption of the starlight by dust in the disk of our Galaxy. The thin streaks of light on the right of the photograph are due to the "zodiacal light", which is caused by the reflection of sunlight off dust in the Solar neighborhood.
